

## Fourier Series

There are series of sines and cosines such as those we found when solving the heat equation. We need to study these series more carefully.

### Preliminaries

Even, odd and periodic functions (17.2)

$f$  is even if  $f(x) = f(-x)$

$f$  is odd if  $f(-x) = -f(x)$

Notice that

- even + even = even
- odd + odd = odd
- even  $\times$  even = even
- odd  $\times$  odd = even
- odd  $\times$  even = odd

If  $f$  is odd then  $\int_{-A}^A f(x) dx = 0$

If  $f$  is even then  $\int_{-A}^A f(x) dx = 2 \int_0^A f(x) dx$ .

Any function can be written as a sum of even and odd functions:

$$f(x) = \underbrace{\frac{f(x) + f(-x)}{2}}_{\text{even}} + \underbrace{\frac{f(x) - f(-x)}{2}}_{\text{odd}}$$

$$\begin{aligned} \text{e.g. } f(x) = e^x &= \frac{e^x + e^{-x}}{2} + \frac{e^x - e^{-x}}{2} \\ &= \cosh(x) + \sinh(x) \end{aligned}$$

If  $f(x+T) = f(x)$  we say that  $f$  is periodic with period  $T$ .

eg.  $\sin x$

$\sin x$  is periodic with period  $2\pi$ .

$\cos x$  " " " "  $2\pi$

$\tan x$  " " " "  $2\pi$

in fact  $\tan x$  has period  $\pi$  as well.

If  $f$  has period  $T$  then it also has period  $2T, 3T$ , etc. The smallest period of a function is called its fundamental period.  $\tan x$  has fundamental period  $\pi$ .

Fourier series of a periodic function. 17.3.

The functions  $\cos \frac{n\pi x}{l}$ ,  $n=0, 1, 2, \dots$

and  $\sin \frac{n\pi x}{l}$ ,  $n=1, 2, \dots$  each have period  $2l$

So if  $f(x)$  has period  $2l$ , can we write

$$f(x) = \sum_{n=0}^{\infty} a_n \cos \frac{n\pi x}{l} + \sum_{n=1}^{\infty} b_n \sin \frac{n\pi x}{l}$$

$$\text{or } f(x) = a_0 + \sum_{n=1}^{\infty} a_n \cos \frac{n\pi x}{l} + b_n \sin \frac{n\pi x}{l}.$$

### orthogonality equations

$$\textcircled{1} \int_{-l}^l \frac{\sin m\pi x}{l} \frac{\sin n\pi x}{l} dx = \begin{cases} 0 & m \neq n \\ l & m = n \end{cases}$$

$$\textcircled{2} \int_{-l}^l \frac{\cos m\pi x}{l} \frac{\cos n\pi x}{l} dx = \begin{cases} 0 & m \neq n \\ l & m = n \neq 0 \\ 2l & m = n = 0. \end{cases}$$

$$\textcircled{3} \int_{-l}^l \frac{\sin m\pi x}{l} \frac{\cos n\pi x}{l} dx = 0.$$

You can prove these the same way that we proved the equations for sine over the interval  $[0, l]$  earlier. Note that  $\textcircled{3}$  is obvious because the integrand is odd (odd = odd  $\times$  even).

Hence if

$$f(x) = a_0 + \sum_{n=1}^{\infty} a_n \frac{\cos n\pi x}{l} + b_n \frac{\sin n\pi x}{l}$$

Formally, multiply each side by  $\frac{\sin m\pi x}{l}$

and integrate from  $-l$  to  $l$ . Because of

the orthogonality, only the  $n=m$  sine term contributes to the sum on the RHS

so

$$\int_{-l}^l f(x) \sin \frac{m\pi x}{l} dx = \int_{-l}^l b_m \sin^2 \frac{m\pi x}{l} dx$$

$$= l b_m$$

$$\text{so } b_m = \frac{1}{l} \int_{-l}^l f(x) \sin \frac{m\pi x}{l} dx$$

Similarly

$$a_m = \frac{1}{l} \int_{-l}^l f(x) \cos \frac{m\pi x}{l} dx \quad m \geq 1$$

But  $a_0$  is different. Integrate each side from  $-l$  to  $l$

$$\int_{-l}^l f(x) dx = \int_{-l}^l a_0 dx = 2l a_0$$

$$\text{so } a_0 = \frac{1}{2l} \int_{-l}^l f(x) dx = \text{average value of } f$$

Piecewise continuity A function  $f(x)$  is piecewise

continuous on an interval  $a \leq x \leq b$  if there exists a finite number of points  $x_1, x_2, \dots, x_N$  such that  $f(x)$  is continuous on each open interval  $(a, x_1)$ ,  $(x_1, x_2)$ ,  $(x_2, x_3)$ ,  $\dots$ ,  $(x_{N-1}, x_N)$ ,  $(x_N, b)$  and has a finite limit as  $x$  approaches each endpoint of these intervals from the insides of the intervals.

Example  $f(x) = \begin{cases} x, & -1 \leq x < 0 \\ 1, & 0 \leq x \leq 1 \end{cases}$

$f(x)$  is piecewise continuous because it is continuous on  $(-1, 0)$ , and on  $(0, 1)$  and because as  $x$  over

approaches  $-1$  in  $(-1, 0)$ ,  $f(x)$  approaches  $-1$ ;  
 as  $x$  approaches  $0$  in  $(-1, 0)$ ,  $f(x)$  "  $0$ ;  
 as  $x$  "  $0$  in  $(0, 1)$ , " "  $1$ ;  
 as  $x$  "  $1$  in  $(0, 1)$ , " "  $1$ .

Notation The left limit of  $f(x)$  at  $x=c$  is denoted  $f(c^-)$  and the right limit is denoted  $f(c^+)$ . Thus, in the example above,

$$\begin{aligned}
 f(-1^+) &= -1 \\
 f(0^-) &= 0 \\
 f(0^+) &= 1 \\
 f(1^-) &= 1
 \end{aligned}$$

### Fourier Convergence Theorem

Let  $f$  and  $f'$  be piecewise continuous on  $[-1, 1]$ , where  $f$  is a  $2l$ -periodic function. Then the Fourier series of  $f$  converges to  $f(x)$  at each point  $x$  at which  $f$  is continuous, and to the mean value

$$\frac{1}{2}(f(x^-) + f(x^+))$$

at each point at which  $f$  is not continuous.

### Example (Saw-tooth)

$f$  and  $f'$  piecewise continuous. In fact,  $f$  is continuous so the Fourier series converges to  $f(x)$ .

Example Square wave

The Fourier series converges to

Let's calculate it:

$$l = \pi$$

$$a_0 = \frac{1}{2l} \int_{-l}^l f(x) dx = \frac{1}{2\pi} \int_0^{\pi} 4 dx = 2$$

$$a_n = \frac{1}{l} \int_{-l}^l f(x) \cos nx dx = \frac{1}{\pi} \int_0^{\pi} 4 \cos nx dx$$

$$= \frac{1}{\pi} \left[ \frac{4 \sin nx}{n} \right]_0^{\pi} = 0$$

$$b_n = \frac{1}{l} \int_{-l}^l f(x) \sin nx dx = \frac{1}{\pi} \int_0^{\pi} 4 \sin nx dx$$

$$= \frac{1}{\pi} \left[ -\frac{4 \cos nx}{n} \right]_0^{\pi} = \frac{-4}{n\pi} (\cos n\pi - 1)$$

$$= \frac{4}{n\pi} (1 - (-1)^n)$$

$$\text{So } f(x) = 2 + \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{1 - (-1)^n}{n} \sin nx$$

Make sure that you put myfourier.m in a folder and then set the current directory of Matlab to be this folder. Then just type the following into the command window.

```
>> x=linspace(-pi,pi);  
>> plot(x,myfourier(x,7),x,myfourier(x,1000))  
>>
```

Here's a listing of the Matlab file:

```
function y=myfourier(x,k)  
%  
% Calculates the sum of the first k terms of a Fourier series.  
L = pi;  
a0 = 2;  
y = a0;  
  
for n = 1:k  
    an = 0;  
    bn = 4*(1-(-1)^n)/(n*pi);  
    y = y + an * cos(n*pi*x/L) + bn * sin(n*pi*x/L);  
end
```
